### Abstract

Lately, mining moths were observed in apple orchards with very strong attacks. Emergence of strong infestations depends on many factors, but the most important climatic factor is temperature. It is known that in plant protection, climatic conditions have a very important role in pest evolution. In 2010 – 2011, at S.C.D.P. Iași was followed the evolution of mined insects, in apple orchard, through an analysis of climatic factors. Observations were made on the predominant species: *Phyllonorycter corylifoliella* Hbn and *Phyllonoryctre blancardella* F. In both species was monitored the dynamic attack depending on weather conditions, which were taken by the AgroExpert Weather Station. Following biological observations, was found that in 2010, the emergence of biological stages for both species was achieved much earlier than in 2011. It depends on climatic factors, especially temperature, factors that determine the number of generations for these pests. In the environmental conditions of Iasi county, both species (*Phyllonorycter blancardella* and *Phyllonorycter corylifoliella*) showed 3 generations per year.

**Key words:** biology, mining moth, climatic factors, evolution;

### INTRODUCTION

Many pests, especially moths, can cause severe damage to agricultural systems, although not all moths are pests of agriculture. (Armelle V., and colab 2005). Between all the pests, a group of microlepidoptere - mining moths was noted recently by strong and powerful attacks in the apple orchards (Drosu Sonica and colab.,1995). The emergence of strong infestations depends on many factors, most important climatic factors, especially temperature. It is known that, in plant protection, climatic conditions have an important role in the evolution of pests. Micro-lepidopteran biology knowledge is very important, especially when control measures are required (Beșleagă Ramona and colab, 2008; Cardei E., Beșleagă Ramona, 2009). In 2010-2011, at Station for Research-Development in fruit Growing Iași, a major development was monitored mined insects encountered in apple orchard, through an analysis of climatic factors.

### MATERIAL AND METHOD

Research on mining moth evolution were developed during 2010 - 2011, in a grove of apple in the S.C.D.P. Iași.

Observations were made on the predominant species: *Phyllonorycter corylifoliella* Hbn and *Phyllonoryctre blancardella* F. Species identification was done by direct observation in the orchard. Their determination was performed at Stereomicroscope by collecting biological material consisting in leaves which were attacked by insects, in various stages of development.

In both species was monitored the dynamic of evolution and attack depending on weather conditions.

Analysis of climatic conditions for the period of observation was made by AgroExpert Weather Station.

### RESULTS AND DISCUSSION

From observations made between 2010 – 2011 it appears that environmental conditions of Iasi county, both species (*Phyllonorycter blancardella* and *Phyllonorycter corylifoliella*) had 3 generations per year.

The results of biological observations taken at S.C.D.P. Iași were presented in tables 1 and 2.

Development and reproduction is conditioned on a complex climatic factors (Pașol P. and colab., 2007). Emergence of biological stages was correlated with a value of effective temperature. The observations made in 2010 found that for both species, the first adults emerged earlier: April 19 for *Phyllonorycter blancardella* species and May 5 for *Phyllonorycter corylifoliella*, different from 2011, when adults emerged later (April 28 – *Phyllonorycter blancardella* and May 10 for *Phyllonorycter corylifoliella*). Analyzing the data shows that for all other stages of development (pupae, larvae and eggs) their first appearances took place earlier in the year 2010 compared to 2011. This is due to

climatic factors, especially temperature, factors that determine the number of generations for these pests (table 2). In tables 3 and 4 are shown the mean daily temperature ( $t_n$ ) and  $\sum$  of effective temperature  $\sum(t_n-t_0)$ , for 2010 and 2011, which exceeded the biological limit ( $t_0$ ). From both tables we can see that average temperatures recorded in 2010 were higher than in 2011. For example, the number of days with temperatures below 6°C (biological limit), recorded in April 2011 were 7 (days), to 2010, when in the same month there is no day below 6°C recorded. In 2010-2011, there were a number of deviations from normal values, such as those in the fall of 2010.

## CONCLUSIONS

In conclusion, we can say that 2010 was a warmer, especially in autumn, and 2011 with normal heat, but dry, especially in the second half.

Correlating all the results above, we can say that the life cycle of mined insects, in the climatic conditions of Iasi county, has three generations per year, such as: for *Phyllonorycter blancardella* species, the evolution was presented as: G I April - June; G II: June - July; G III: July – September, and for *Phyllonorycter corylifoliella*: G I: May - June; G II: June - July; G III: July – March (next year).

- life cycle of the two presented insects (*Phyllonorycter blancardella* and *Phyllonorycter corylifoliella*) they had 3 generations per year.

- *Phyllonorycter corylifoliella* hibernate as mature larvae and larvae first appear in the first decade of May.

- *Phyllonorycter blancardella* hibernate as pupae and adults are making their first appearance in April;

- the temperatures recorded in 2010 – 2011, have favorably influenced the evolution of mined insects;

- micro-lepidopteran biology knowledge is very important, especially when control measures are required.
