The range of irrigated crops is adequate if offer the tillage possibility of reclamation project of land by all during the vegetation period through double crops practice. In outside of supplementary production, the double crops contribute at prevention of secondary salinization process of soil and on sloping lands at diminution of erosion process. The analysis of energetically values for obtained yield at different agricultural plants, which are established like successive crops in different pedoclimatics zones into Romania, allowed the established for most adequate combinations of forerunners plants - double crops, sowing epoch and variants of fertilization.
