

Cresterea potentialului productiv al pajistilor permanente de deal si munte sub influenta tarlirii si fertilizarii suplimentare cu ingrasaminte chimice

IONESCU I., OSICEANU M., COLA M. - Universitatea din Craiova

The research done on the meadows from the mountain area dominated by *Nardus stricta* and on the meadows from the hilly area dominated by *Agrostis capillaris* demonstrated that the maintaining of the animals for rest in the same place for 2 nights and the supplementary supply with reduced nitrogen doses (50-60 kg/ha) together with phosphorus and potassium constitutes a recommended solution for the improvement of the degraded meadows. There is an important yield increase and there are respected the environmental protection norms.
