The paper presents the evolution of the changing coefficients of the evaporation from the .A. class evaporation tank to crops water consumption depending on the vegetation phases, for eight crops, in the pedoclimate conditions of the south-east of the Moldavian Plain. Such an approach of the problem permit to simulate the daily consumption depending on the development degree of the plant without any connection with the factor time which is very difficult to be strictly controlled in the case of a great number of fields within a crop rotation, with different days of the sowing and/or rising.
