

Researches regarding earth slides from batin locality, Unguras commune, Cluj district

M. DIRJA, V. BUDIU, I. PACURAR, M JURIAN - USAMV Cluj-Napoca

General configuration of Romanian relief, with many slope terrains, offers a great favourability to the start and evolution of slide process. Only in the last major cycle of the earth slide reactivation, the process has started on 110.000 ha, in arable or forest surface). In Romania, the total surface affected by earth slide is over 790.000 ha. From this about 670.000 ha are arable land. The pastures are the most affected due to the fact that are usually very damaged and due to irrational pasturing. It should taken measures to prevent and struggle against earth slide because this phenomenon affects a great surface and the damages to the localities, communication lines and arable lands are very high.
