

Human resource and agricultural environment. Productivity and degree of utilization

LUP A. - "Ovidius" University Constanta

The author analyses the evolution of the agricultural land, its productivity and occupation degree of the rural people in the Romanian space. There are compared for a long time the evolution of the agricultural land, its productivity and degree of using of the yearly labour time. During a century — 1900-2000 — agricultural cultivate area has increased from 2.4 ha/active person to 2.6 ha/active person. In the same period the number of the workdays have been reduced from more than 40 days per cultivated ha to about 3 days per ha associated with a corresponding gain in work productivity. The prognoses concerning the land productivity are very optimistic, especially in work productivity but not in the case of the agricultural employment which can become the main crisis of the romanian agriculture.
