In this paper we indicate some physical and chemical methods of analysing the honey in order to establish honey quality and cleanliness and to set up the degradation level. Using these methods of analyse we establish the ash percent, honey acidity, inverted sugar content and sucrose content. The results obtain were compared with the range proposed by the European Union. Honey must respect some technical condition in order to be merchandised. The analyses were done on 3 samples of honey: locust tree honey, linden tree honey and poly- flowers honey. The honey samples were collected from hives situated in the experimental field, which is located in Glimboca village, Caras-Severin County.
