Irrigation in the greenhouse has a decisive rol. The drip irrigation technique with automatic work represents the most modern method. The paper presents the technical solution for small surfaces, under 3 ha. The automatic work is made for two main ways of action, by the activating the soil moisture sensor or by the choosing a watering programme depending on the watering duration and the interval between waterings. In the automatic method work of Senzor can be performed with one secondary method. There are presented other useful prompts in the regulation of the installation and elements of cost.
